Cutting wedge technology: Liver disease can be spotted by CHEESE scanner

23:59, 26 NOV 2013 | BY ANDREW GREGORY

Originally developed for farmers to test the ripeness of their product, medics have now found it can detect the life-threatening condition

Say cheese: Life-saving technology

When? Screening cirrhosis/P Hypertension

Before

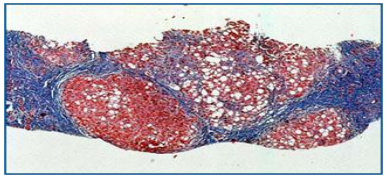
- **Clinically suspected or evident**
- **Signs, Labs, Imaging**
- **Liver biopsy**
- **Decompensation**

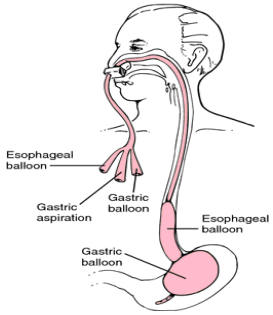
Now

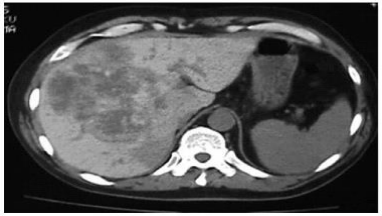
- **Always**
- **Non-invasive tests**

Pre-elastography era: unsuspected cirrhosis

- **Diabetes**
- **ALT 35**
- **GGT 60**
- **US steatosis**
- **Diet, weight**



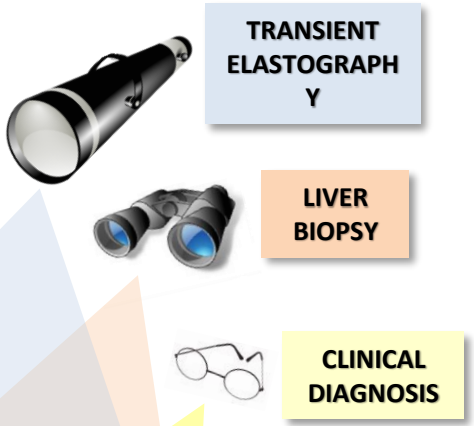




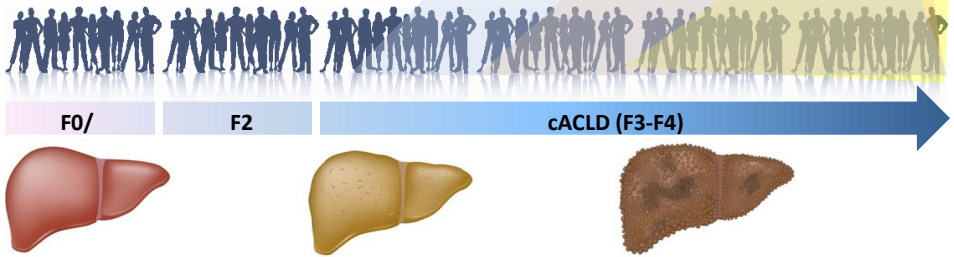
Impact of elastography in CLD

- Liver (spleen) stiffness by elastography (TE)
- CLD staging
- Essential to non-invasive assessment of CLD

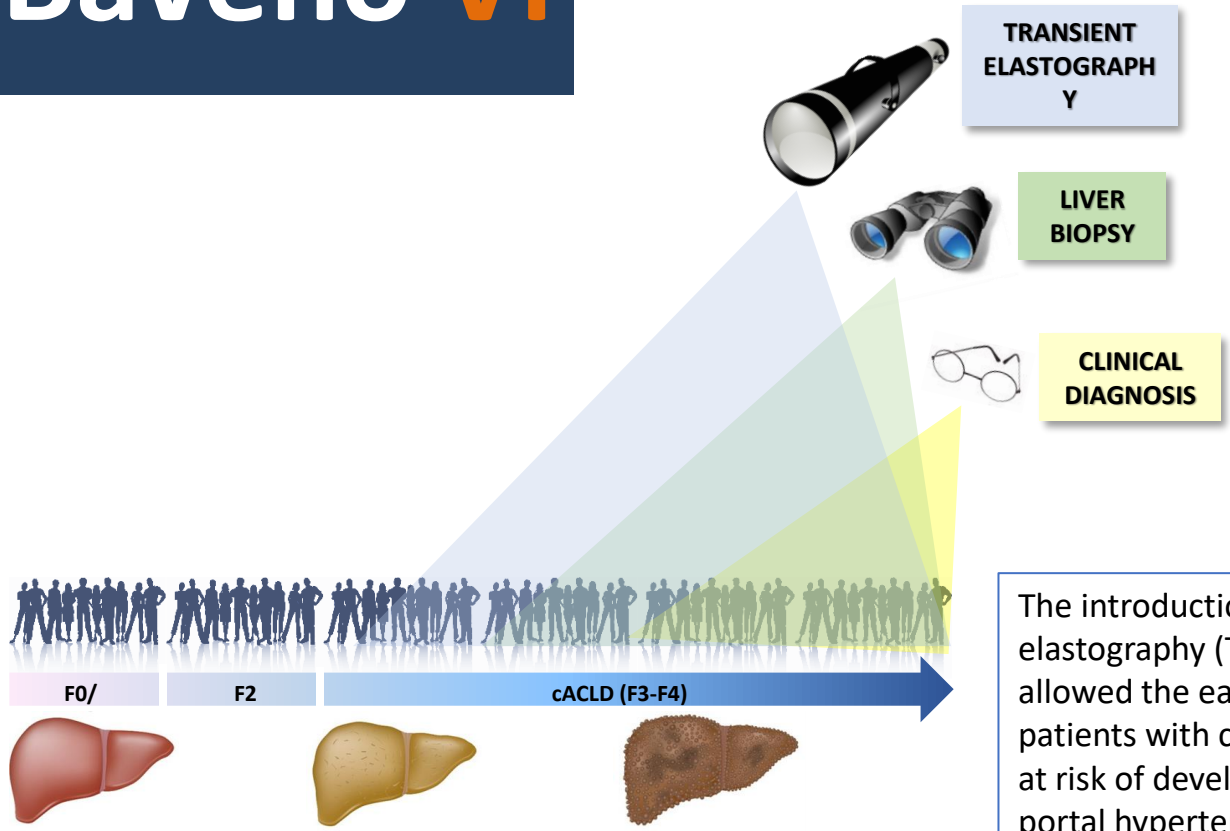
Applicability
Easiness
Repeatable
Rapidness



CHRONIC LIVER DISEASE



Baveno VI



The introduction of transient elastography (TE) in clinical practice has allowed the early identification of patients with chronic liver disease (CLD) at risk of developing clinically significant portal hypertension (CSPH) (1b; A).

Baveno VI

Compensated Advanced Chronic Liver Disease (cACLD)

LIVER STIFFNESS

< 10 kPa | **> 15 kPa** | **< 10 kPa** | **> 15 kPa**

FIBROSIS STAGE (F3-F4) → **RISK OF LRE (DECOMP/L. DEATH)**

Study	Etiology	Patients (n)	Liver event	Follow-up (months)	LSM cut-off	Event rate
Masuzaki et al. 2009 [10]	HCV	866	HCC	36 (mean)	≤10 kPa	CI: 0.4% (3 years) ER: 2/511 (0.4%)

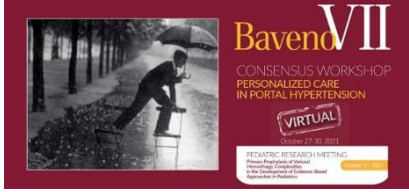
CONSENSUS WORKSHOP
PERSONALIZED CARE IN PORTAL HYPERTENSION
October 27-30, 2021

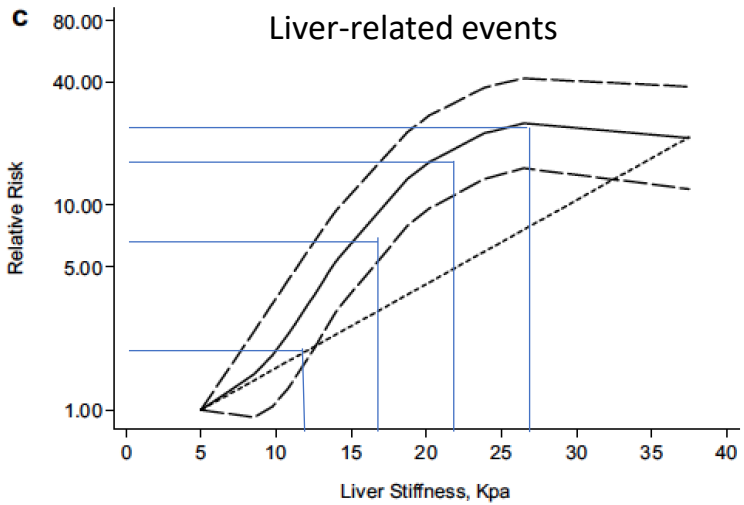
Outcome and Prognosis (All New)

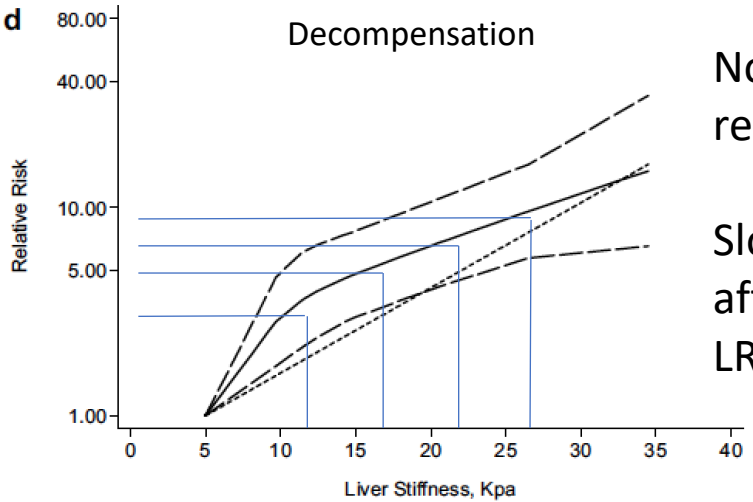
-LSM (irrespective of the technique used for its measurement) holds prognostic information in cACLD, both at index investigation and during follow-up (A;1).

-A rule of five for LSM by TE (10-15-20-25 kPa) should be used to denote progressively higher relative risks of decompensation and liver-related death independently of the etiology of CLD (B;1).



Dose-response between LSM and LRE or decompensation





N>3,000 for LRE
N>6,000 for decompensation

Non-linear dose-response.

Slope flattens after 25 kPa for LRE.

Updated Recommendations

Panel 3/session 2, part 2

“Impact of aetiological therapies in the course of cirrhosis”

Suggested new title: “Portal hypertension management after removal/suppression of the primary etiological factor”

Panel 3/session 2, part 2 – "Impact of aetiological therapies in the course of cirrhosis"

- **B7: "Patients with HCV-induced cACLD who achieve SVR and show post-treatment improvements to liver stiffness measurement (LSM) values of <12kPa and PLT >150,000 can be discharged from portal hypertension surveillance, as they do not have CSPH. In the identified low-risk patients, HCC surveillance is the main concern."**

- Comment: New statement based on the individual patient data meta-analysis (uploaded; REF 1) the sensitivity of these criteria for CSPH is 99%; the reason for using such stringent criteria is that otherwise, in a very selected dataset (based on REF 2) of patients with pre-treatment CSPH who did not resolve CSPH 24 weeks after end of treatment and in whom HVPG was repeated at week 96 (i.e., a highly selected patient population), a relevant proportion of patients with CSPH would have been missed – for "discharging" patients, we want to be on the safe side. The risk of decompensation for patients meeting these criteria is 0% (based on REF 3), if considering HCC as a competing risk. These criteria are met 37.9% of unselected cACLD patients achieving SVR (based on an unpublished cohort of n=1972 patients). Thus, a relevant proportion of patients can be discharged from portal hypertension surveillance.

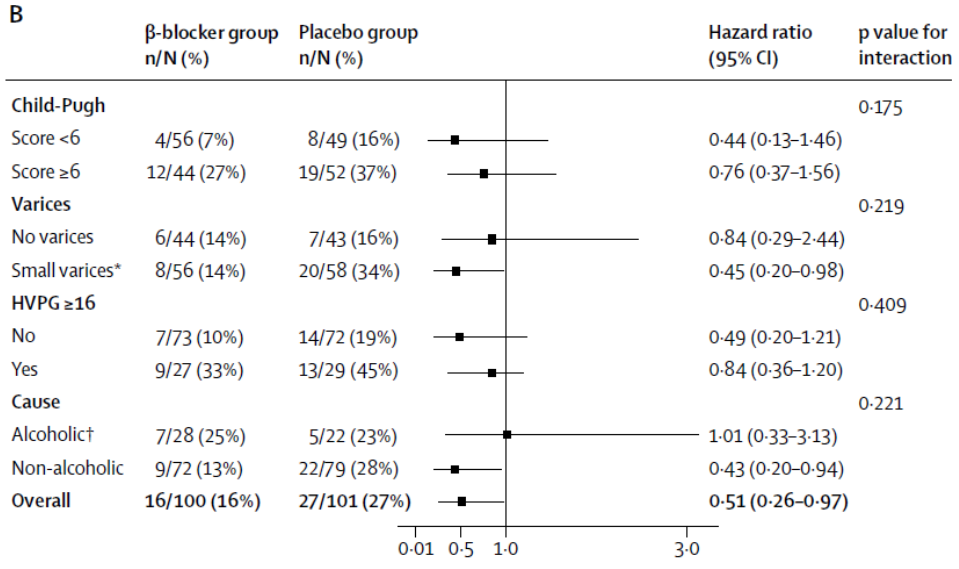
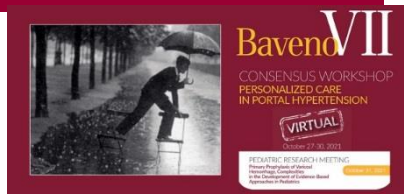
B



-Treatment with non-selective beta-blockers (propranolol, nadolol or carvedilol) is recommended for the prevention of decompensation in patients with CSPH (A1).
-Carvedilol is the preferred NSBB in compensated cirrhosis, since it is more effective in reducing HVPG (A1)…

Villanueva, et al. The Lancet 2019



Elastography: detecting CSPH

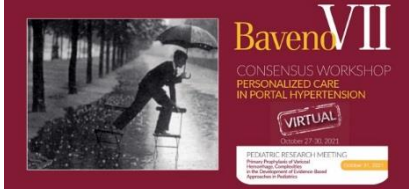
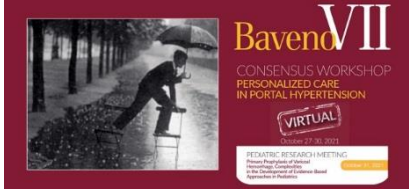
ALD, alcoholic liver disease; CI, confidence interval; HBV, chronic hepatitis B; HCV, chronic hepatitis C; HVPG, hepatic venous pressure gradient; LSM, liver stiffness measurement; NASH, nonalcoholic steatohepatitis.
[a]Number of patients within LSM cutoff.
[b]Number of patients without clinically significant portal hypertension within the LSM cutoff.



Identification of patients with chronic liver disease (viral and alcoholic etiology) at risk of CSPH in the different stages of the disease by using noninvasive tests including liver stiffness.

	STAGES OF CHRONIC LIVER DISEASE						
	No cirrhosis		Early compensated cirrhosis	Late compensated cirrhosis			Decompensated cirrhosis
	CLD	Early cACLD		Late cACLD			dACLD
Liver fibrosis	F1-F2	F3	F4	F4			F4
HVPG (mm Hg)	<5	5 - <10		≥10			≥10
Portal hypertension	No	Mild		CSPH			CSPH
Liver stiffness (kPa)	<10	10-<25		15 - <20	20 - <25	≥25	Unneeded
Platelet count (K/mm^3)	Any	Normal		<110	<150	Any	Any



Session 1: Evaluation and risk stratification

Part 2: Noninvasive tools for cACLD and portal hypertension

Clinically significant portal hypertension (CSPH)

-CSPH: ≥25 kPa ruling in for viral/alcohol and non-obese NASH (>90% PPV, >90% Sp).

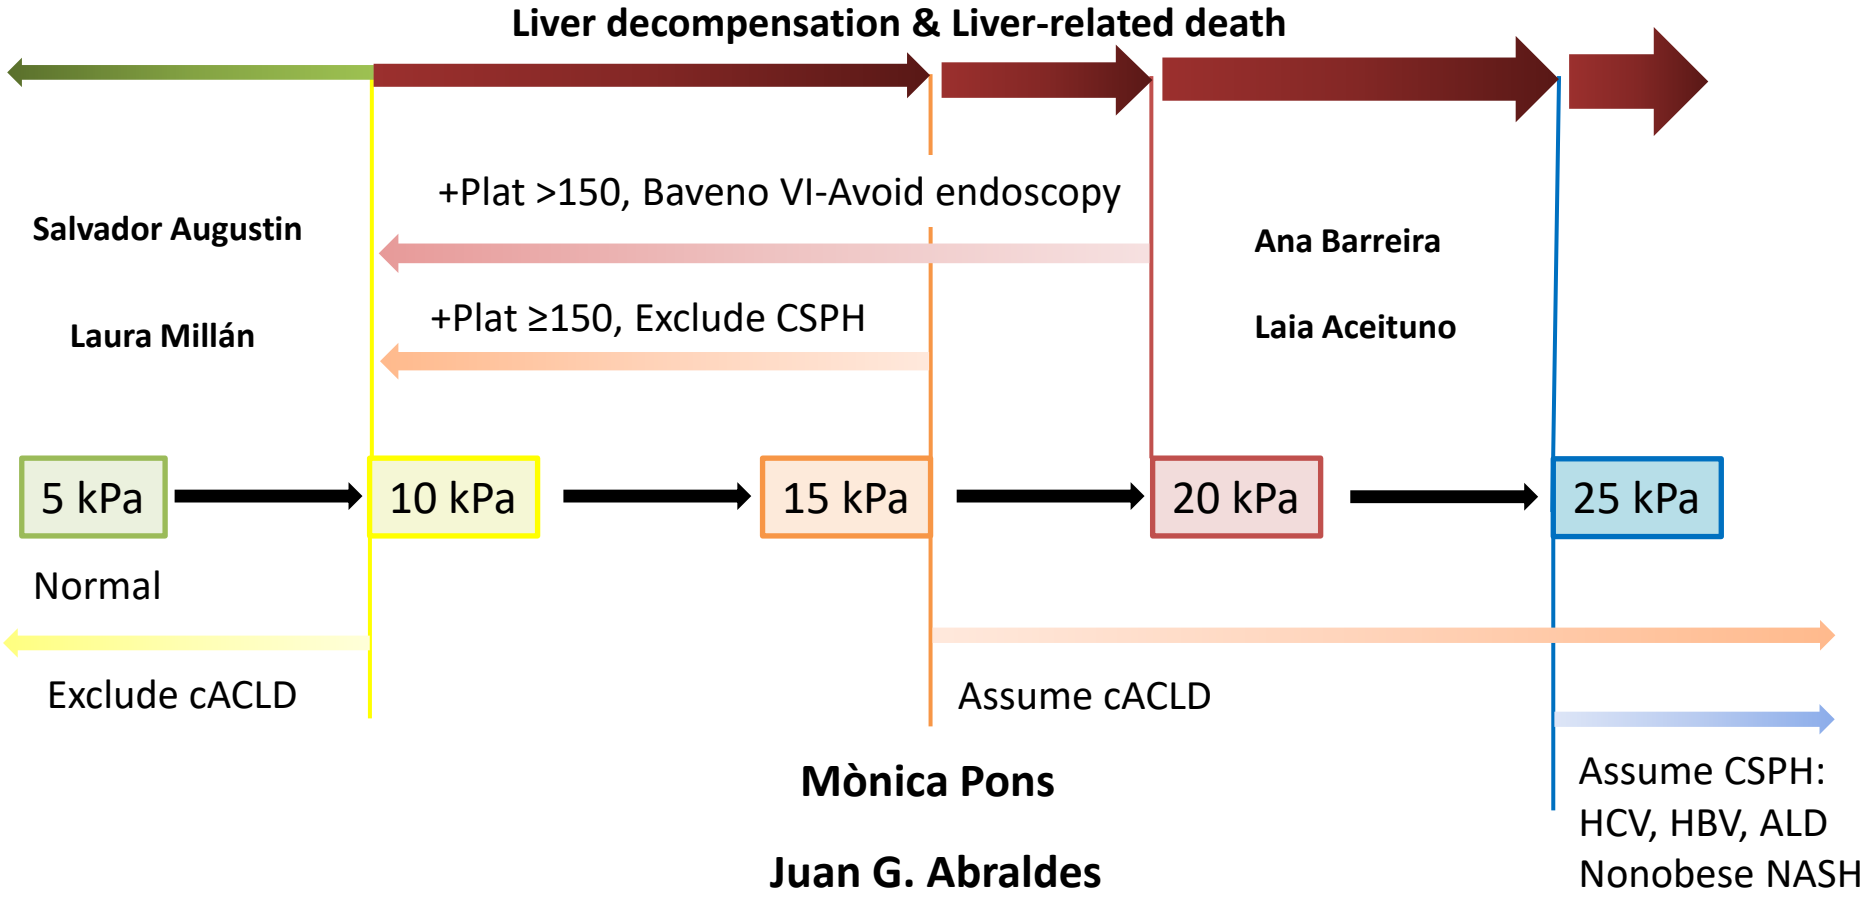
-CSPH: <25 kPa ANTICIPATE model for viral/alcohol (CSPH risk of at least 60%):

  -LSM between 20-25 kPa and platelet count <150x10^9/L.

  -LSM between 15-20 kPa and platelet count < 110x10^9/L.

-CSPH for NASH: NASH-ANTICIPATE model: see table with practical examples based on model prediction.

-Ruling out CSPH: ≤15 kPa + pla ≥150 (>90% NPV, >90% Se).



Non-invasive prediction in cACLD by TE-summary: THE RULE OF FIVE
